Ranula refers to a collection of extra-glandular and extraductal saliva in the floor of the mouth originating from the sublingual salivary gland. It may rarely originate from injury to the submandibular gland (SMG) duct. It is a pseudocyst, as it does not contain an epithelial lining.

It classically presents as a soft submucosal swelling in the floor of the mouth (Figure 1). The term *ranula* originates from the Latin word for frog (*rana*) as the cyst is said to look like the underbelly of a frog.

A *plunging ranula* extends into the submandibular triangle of the neck through a defect in the mylohyoid muscle, or less commonly, by passing behind the posterior edge of the muscle (Figure 2).

A ranula may also track posteriorly along tissue planes into the parapharyngeal space (Figure 3).

The simplest way to clinch the diagnosis is by examining a needle aspirate of the typically thick, straw colored saliva (Figure 4).
Treatment of a ranula is controversial, and includes marsupialization, excision of the sublingual salivary gland, excision of the ranula +/- excision of the sublingual salivary gland, and sclerotherapy. Excising the sublingual salivary gland is the key to minimizing recurrence and is the author’s preference.

**Surgical anatomy**

The paired *sublingual salivary glands* are located beneath the mucosa of the anterior floor of mouth, anterior to the submandibular ducts and above the mylohyoid and geniohyoid muscles (Figures 5, 6, 7). The glands drain via 8-20 excretory ducts of Rivinus into the SMG duct and also directly into the mouth on an elevated crest of mucous membrane called the *plica fimbriata* which is formed by the gland and is located to either side of the frenulum of the tongue (Figures 6 & 7).

The *lingual nerve* crosses deep to the submandibular duct in the lateral floor of mouth. In the anterior floor of mouth it is located posterior to the duct (Figures 5 & 6).

The *submandibular duct* is located immediately deep to the mucosa of the anterior and lateral floor of mouth, and opens into the oral cavity to either side of the frenulum (Figures 5 & 6).

*Ranine veins* are visible on the ventral surface of the tongue, and accompany the hypoglossal nerve (Figure 8).

The detailed surgical anatomy of the SMG and submandibular triangle are dealt with in detail in the chapter on submandibular gland excision.
**Operative steps**

The following description applies to excision of a simple ranula, the sublingual salivary gland, and a plunging ranula.

**Anaesthesia**

A broad-spectrum antibiotic is administered for 24 hours. With excision of a plunging ranula the anaesthetist should avoid muscle paralysis as it is useful to monitor the movement of the lower lip should the marginal mandibular nerve be surgically irritated.

**Positioning and draping**

The patient is placed in a supine position with neck extended. The skin of the anterior neck and lower face is sterilised. Draping is done in such a way that the mouth and upper neck are exposed. A self-retaining retractor is used to open the mouth. A silk traction suture is passed through the tip of the tongue to better expose the anterior floor of the mouth.

**Excision of a simple ranula (Figure 1)**

The mucosa is incised over the ranula taking care not to enter the sac. A submucosal dissection plane is established over the wall of the ranula. Using sharp and blunt dissection, the cyst is excised, taking care not to injure the submandibular duct or the lingual nerve. Should the submandibular duct be injured, then it is simply translocated to the lateral floor of mouth by mobilising the duct, and passing it through a stab incision in the mucosa of the lateral floor of mouth. It is secured to the oral mucosa with a suture passed through the side of the duct (Figure 9).

**Excision of sublingual salivary gland**

The sublingual gland is surprisingly large, and is located immediately deep to the mucosa just anterior to the submandibular duct in the anterior floor of mouth. It may be excised by using electrocautery and blunt dissection (Figure 10). Structures at risk of injury are the submandibular duct and lingual nerve (Figure 11).

**Figure 9**: Submandibular duct transposed to right lateral floor of mouth, and sutured to mucosa with a vicryl suture

Excision of plunging ranula

While a plunging ranula may resolve by simply excising the sublingual salivary gland, some surgeons prefer also to excise the ranula.

Readers are referred to the chapter on submandibular gland excision for the surgical anatomy, as much of the dissection is similar. A horizontal incision, placed in a skin crease and at least 3cms below the mandible or at the level of the hyoid bone, and extending anteriorly from the anterior border of the sternocleidomastoid muscle, is made through skin, subcutaneous tissue and platysma. The common facial and anterior facial veins are identified posteriorly, and divided and ligated if required for access. The ranula is identified in the anterior part of the submandibular triangle (Figure 12).

The anterior belly of digastric is identified and retracted anteriorly. The mylohyoid muscle is identified deep to and behind the anterior belly of digastric (Figure 13).

The surgeon may have to mobilise and resect the SMG for better access (Figure 14). The ranula is mobilised with sharp and blunt dissection from the surrounding muscles and the SMG posteriorly. It is traced to where it generally passes through a de-
